Category:Educational psychologyPerspectives of the poxvirus family: a drug discovery perspective. The members of the poxvirus family are divided into three subfamilies, based on genome sequence information. A major evolutionary divergence was indicated in the Laxmanan subfamily by the identification of a species-specific gene that appears to be involved in virus pathogenicity. Vaccinia virus stands out from other poxvirus members because of its unique ability to cause a systemic disease that results in an immune response capable of protecting against future disease. Live virus vaccines provide the best protection against poxviruses, but attenuated vaccines that have been generated by selecting for attenuation in cell culture or for smallpox virus-induced lesions also provide protection. A number of other poxvirus genomes are being made publically available, and the possibility exists that the definition of poxvirus function will be translated into improvement in poxvirus-derived biological products. Poxvirus proteins are also being exploited in an increasing number of applications in the biotechnology industry.Q: ASP.NET MVC3 - Form POST not matching model I have a pretty basic issue. I have a partial view which renders a form of the properties of a Product object which should be set based on some state from the controller (which sets a boolean flag on the Product object). This is my form: @model Product @using (Html.BeginForm("Create", "Products", FormMethod.Post, new { id = "product_form" })) { @Html.AntiForgeryToken() @Html.ValidationSummary() @Html.EditorFor(model => model.Created, new { htmlAttributes = new { @class = "form-control" } }) @Html.ValidationMessageFor(model => model.Created, "", new { @class = "text-danger" }) } The problem is that when this renders, the form's submitted value has no posted value, since it is using the f678ea9f9e
